## ABSTRACT

In this paper we examine the somewhat controversial subject of energy consumption of networking devices in the Internet, motivated by data collected by the U.S. Department of Commerce. We discuss the impact on network protocols of saving energy by putting network interfaces and other router & switch components to sleep. Using sample packet traces, we first show that it is indeed reasonable to do this and then we discuss the changes that may need to be made to current Internet protocols to support a more aggressive strategy for sleeping. Since this is a position paper, we do not present results but rather suggest interesting directions for core networking research. The impact of saving energy is huge, particularly in the developing world where energy is a precious resource whose scarcity hinders widespread Internet deployment.

## 1. INTRODUCTION

Recently, an opinion has been expressed in various quarters (see [5, 12]) that the energy consumption of the Internet is “too high” and that since this energy consumption can only grow as the Internet expands, this is a cause for concern. One may disagree, as we do, with the qualitative statement that the energy consumption of the Internet is too high, because it is a small fraction of the overall energy

Device	Approximate Number Deployed	Total AEC TW-h
Hubs	93.5 Million	1.6 TW-h
LAN Switch	95,000	3.2 TW-h
WAN Switch	50,000	0.15 TW-h
Router	3,257	1.1 TW-h
Total		6.05 TW-h

Table 1: Breakdown of energy draw of various networking devices (TW-h refers to Tera-Watt hours and AEC to Annual Electricity Consumption).

consumption. However, the absolute numbers do indicate a need to be more energy efficient. We use the analysis presented by these observers as a starting point to discuss an exciting new direction for future core networking research. We believe that if energy can be conserved by careful engineering then there is no reason why we should not do so as this has implications not only for reducing energy needs in the U.S. but also on speeding up Internet deployment and access in the developing world where energy is very scarce.

Table 1 [14] summarizes the energy consumption by Internet devices in the U.S. as of the year 2000. These values are copied from Tables 5-59 (Hub), 5-61 (LAN switch), 5-62 (WAN switch), and 5-64 (Router) of [14]. The data is broken up based on network device type, which is useful in analyzing where and how energy savings can be garnered. In order to arrive at the various energy numbers in the table, the authors took into account the percentage of different types of devices deployed (e.g., number of CISCO 2500 type routers, number of 7505s, etc) and then used the average energy consumption values of these devices to arrive at the final numbers shown in the table<sup>1</sup>. Two energy values missing from the table are the energy cost of *cooling* the equipment and that of UPS (Uninterruptible Power Supplies) equipment<sup>2</sup>. The future expectation is that the energy consumption of networking devices will increase by 1 TW-h by 2005 [14].

Expressed as a percentage of total U.S. energy expenditure in the year 2000, the energy drawn by the devices in Table 1 accounts for approximately 0.07% of the total. Given that this is almost negligible in comparison to other energy

<sup>1</sup>Note that the energy draw varies based on load and the values used in this study are based on observed average values.

<sup>2</sup>According to [14], air conditioning in data centers containing routing equipment costs approximately 20 – 60 Watts/ft<sup>2</sup>.

## Reducing Network Energy Consumption via Sleeping and Rate-Adaptation

Sergiu Nedevschi<sup>+†</sup> Lucian Popa<sup>\*†</sup> Gianluca Iannaccone<sup>†</sup>  
Sylvia Ratnasamy<sup>†</sup> David Wetherall<sup>‡§</sup>

### Abstract

We present the design and evaluation of two forms of power management schemes that reduce the energy consumption of networks. The first is based on putting network components to sleep during idle times, reducing energy consumed in the absence of packets. The second is based on adapting the rate of network operation to the offered workload, reducing the energy consumed when actively processing packets.

For real-world traffic workloads and topologies and using power constants drawn from existing network equipment, we show that even simple schemes for sleeping or rate-adaptation can offer substantial savings. For instance, our practical algorithms stand to halve energy consumption for lightly utilized networks (10-20%). We show that these savings approach the maximum achievable by any algorithms using the same power management primitives. Moreover this energy can be saved without noticeably increasing loss and with a small and controlled increase in latency (<10ms). Finally, we show that both sleeping and rate adaptation are valuable depending (primarily) on the power profile of network equipment and the utilization of the network itself.

### 1 Introduction

In this paper, we consider power management for networks from a perspective that has recently begun to receive attention: the conservation of energy for operating and environmental reasons. Energy consumption in network exchanges is rising as higher capacity network equipment becomes more power-hungry and requires greater amounts of cooling. Combined with rising energy costs, this has made the cost of powering network exchanges a substantial and growing fraction of the total cost of ownership – up to half by some estimates[23]. Various studies now estimate the power usage of the US network infrastructure at between 5 and 24 TWh/year[25, 26], or \$0.5-2.4B/year at a rate of \$0.10/KWh, depending on what is included. Public

via standards such as EnergyStar. In fact, EnergyStar standard proposals for 2009 discuss slower operation of network links to conserve energy when idle. A new IEEE 802.3az Task Force was launched in early 2007 to focus on this issue for Ethernet [15].

Fortunately, there is an opportunity for substantial reductions in the energy consumption of existing networks due to two factors. First, networks are provisioned for worst-case or busy-hour load, and this load typically exceeds their long-term utilization by a wide margin. For example, measurements reveal backbone utilizations under 30% [16] and up to hour-long idle times at access points in enterprise wireless networks [17]. Second, the energy consumption of network equipment remains substantial even when the network is idle. The implication of these factors is that *most* of the energy consumed in networks is wasted.

Our work is an initial exploration of how overall network energy consumption might be reduced without adversely affecting network performance. This will require two steps. First, network equipment ranging from routers to switches and NICs will need power management primitives at the hardware level. By analogy, power management in computers has evolved around hardware support for *sleep* and *performance* states. The former (*e.g.*, C-states in Intel processors) reduce idle consumption by powering off sub-components to different extents, while the latter (*e.g.*, SpeedStep, P-states in Intel processors) tradeoff performance for power via operating frequency. Second, network protocols will need to make use of the hardware primitives to best effect. Again, by analogy with computers, power management preferences control how the system switches between the available states to save energy with minimal impact on users.

Of these two steps, our focus is on the network protocols. Admittedly, these protocols build on hardware support for power management that is in its infancy for networking equipment. Yet the necessary support will readily be deployed in networks where it makes

## Reducing Network Energy Consumption via Sleeping and Rate-Adaptation

Sergiu Nolevschi<sup>1</sup>, Lucian Popa<sup>2\*</sup>, Gianluca Iannaccone<sup>1</sup>, Sylvia Ratnasamy<sup>1</sup>, David Wetherall<sup>1</sup>

### Abstract

We present the design and evaluation of two forms of power management schemes that reduce the energy consumption of networks. The first is based on putting network components to sleep during life times, reducing energy consumed in the absence of packets. The second is based on adapting the rate of network operations to the offered workload, reducing the energy consumed when network processing packets.

For each workload, workloads and topologies and using power consumed above from existing network equipment, we show that even simple schemes for sleeping or rate adaptation can offer substantial savings. For instance, our practical algorithms used to reduce energy consumption for lightly utilized networks (0-20%) We show that these savings approach the maximum achievable by any algorithm using the same power management primitives. Moreover, the energy can be used with-out noticeably increasing loss and with a small and controlled increase in latency (10ms). Finally, we show that both sleeping and rate adaptation are valuable depending (primarily) on the power profile of network equipment and the utilization of the network itself.

### 1 Introduction

In this paper, we consider power management for networks from a perspective that has recently begun to receive attention: the conservation of energy for operating and environmental reasons. Energy consumption in network equipment is rising at higher speeds, network equipment becomes more power-hungry and requires greater amounts of cooling. Combined with rising energy costs, this has made the cost of powering networks a substantial and growing fraction of the total cost of ownership – up to half by some estimates[2]. Various studies now estimate the power usage of the US network infrastructure at between 5 and 24 TWh/year[25, 26], or 60.3-248TWh at a rate

via standards such as EnergyStar. In fact, EnergyStar standard proposals for 2009 discuss direct operation of network links to conserve energy when idle. A new IEEE 802.3az Task Force was launched in early 2007 to focus on this issue for Ethernet[13].

Fortunately, there is an opportunity for substantial reductions in the energy consumption of existing networks due to two factors. First, networks are provisioned for worst case or long-term load, and this load typically exceeds their long-term utilization by a wide margin. For example, measurements reveal backbone utilization under 5% [14] and up to hour-long life times at access points in enterprise-wide networks [17]. Second, the energy consumption of network equipment remains substantial even when the network is idle. The implication of these factors is that most of the energy consumed in networks is wasted.

Our work is an initial exploration of how overall network energy consumption might be reduced without adversely affecting network performance. This will require two steps. First, network equipment ranging from routers to switches and NICs will need power management primitives at the hardware level. By analogy, power management in computers has evolved around hardware support for sleep and performance states. The latter is a goal of IEEE 802.3az (to reduce life-time consumption by powering off sub-components in different states, while the latter is a goal of Speedy-Praxis in host processors) and/or performance for power via operating language. Second, network protocols will need to adapt one of the hardware primitives to be effective. Again, by analogy with computers, power management performance comes from the system interface between the available states to save energy with minimal impact on users.

Of these two steps, our focus is on the network protocols. Admittedly, these protocols build on hardware support for power management that is in its infancy.

## Reducing Network Energy Consumption via Sleeping and Rate-Adaptation

Sergiu Nolevschi<sup>1</sup>, Lucian Popa<sup>2</sup>, Gianluca Iannaccone<sup>1</sup>, Sylvia Ratnasamy<sup>3</sup>, David Wetherall<sup>1</sup>

### Abstract

We present the design and evaluation of two forms of power management schemes that reduce the energy consumption of networks. The first is based on putting network components to sleep during life times, reducing energy consumed in the absence of packets. The second is based on adapting the rate of network operations to the offered workload, reducing the energy consumed when network processing packets.

For each workload, workloads and topologies and using power consumed above from existing network equipment, we show that even simple schemes for sleeping or rate adaptation can offer substantial savings. For instance, our practical algorithms used to reduce energy consumption for lightly utilized networks (0-20%) We show that these savings approach the maximum achievable by any algorithm using the same power management primitives. Moreover, this energy can be used to reduce network energy consumption while not noticeably increasing loss and with a small and controlled increase in latency (10ms). Finally, we show that both sleeping and rate adaptation are valuable depending (primarily) on the power profile of network equipment and the utilization of the network itself.

### 1 Introduction

In this paper, we consider power management for networks from a perspective that has recently begun to receive attention: the conservation of energy for operating and environmental reasons. Energy consumption in network equipment is rising at higher speeds; network equipment becomes more power-hungry and requires greater amounts of cooling. Combined with rising energy costs, this has made the cost of powering networks a substantial and growing fraction of the total cost of ownership – up to half by some estimates[2]. Various studies now estimate the power usage of the US network infrastructure at between 5 and 24 TWh/year[7]. 5% of 50.5-248TWh is a rate

via standards such as EnergyStar. In fact, EnergyStar standard proposals for 2009 discuss direct operation of network links to conserve energy when idle. A new IEEE 802.3az Task Force was launched in early 2007 to focus on this issue for Ethernet[15].

Fortunately, there is an opportunity for substantial reductions in the energy consumption of existing networks due to two factors. First, networks are provisioned for worst case or long term load, and this load typically exceeds their long term utilization by a wide margin. For example, measurements reveal backbone utilizations under 50% [14] and up to hour-long life times at access points in enterprise wireless networks [17]. Second, the energy consumption of network equipment remains substantial even when the network is idle. The implication of these factors is that most of the energy consumed in networks is wasted.

Our work is an initial exploration of how overall network energy consumption might be reduced without adversely affecting network performance. This will require two steps. First, network equipment ranging from routers to switches and NICs will need power management primitives at the hardware level. By analogy, power management in computers has enabled several hardware support for sleep and performance states. The latter is e.g. C-states in Intel processors to reduce idle consumption by powering off sub-components in different states, while the latter is e.g. SpeedStep in Intel Intel processors) to reduce power via operating frequency. Network network protocols will need to take one of the hardware primitives to be effective. Again, by analogy with computers, power management primitives cannot have the system switches between the available states to save energy with minimal impact on users.

Of these two steps, our focus is on the network protocols. Admittedly, these protocols build on hardware support for power management that is in its infancy.

## Energy Savings (%)

With Hypnos?

How much energy  
can we really save? Very little. ( $<1\%$ )

Hyperloop tubes require loads of power to create vacuum, whether used or not.

Because “turned off”  
does **not** always  
mean “powered off.”

Power increases **at plug-in**  
even if the port is “off”!

# We are doing a terrible job at power proportionality today.

Similar problems with internal router components that remain powered on while being configured “off.”

- Thankfully, hardware vendors are starting to notice...
- ... and it is actually easy to fix!

# We are doing a terrible job at power proportionality today. It's a bug.

Similar problems with internal router components that remain powered on while being configured “off.”

- Thankfully, hardware vendors are starting to notice...
- ... and it is actually easy to fix!

Until this gap is addressed, a simple workaround exists: configuring the empty ports in “unused” mode.

In case you wonder  
The usual config  
is “shutdown.”

Don't fill the pipes!

Why we must **keep** the Internet empty.

# Once the network is up, traffic costs almost nothing.

# Once the network is up, traffic costs almost nothing.

The power to send that traffic is

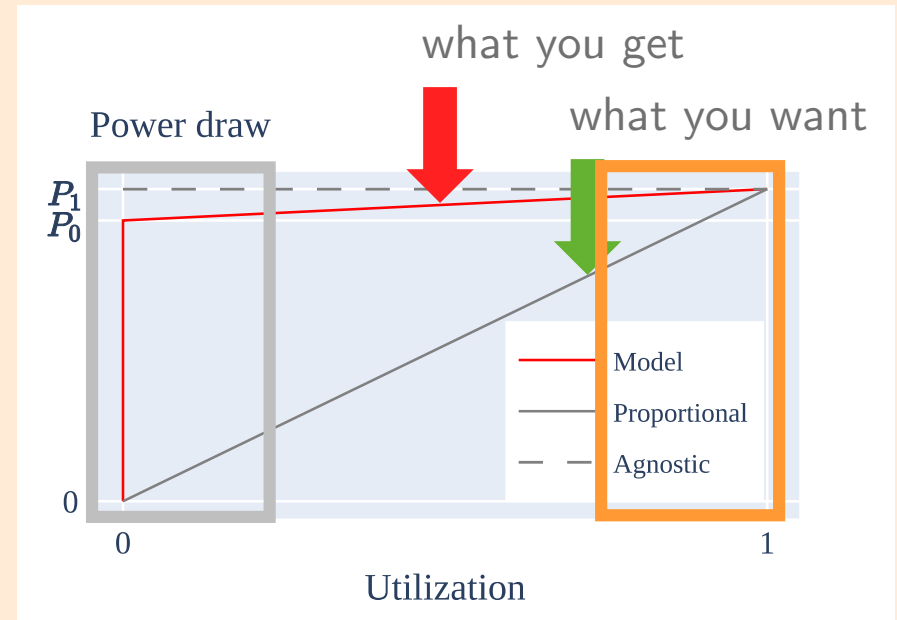

~6W

That's 0.02% of the  
total network power.

# Increasing utilization improves efficiency

- Run more often at high utilization

- Take low-utilization power down

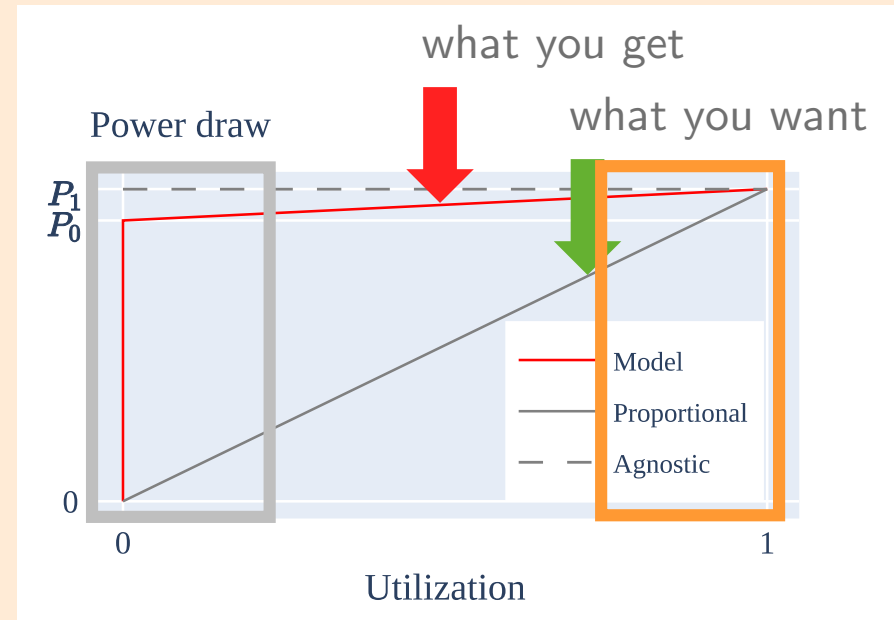

Increasing utilization improves efficiency in the **short** term.

- Run more often at high utilization

- Take low-utilization power down

Increasing utilization improves efficiency in the **short** term.

- Run more often at high utilization

- Take low-utilization power down

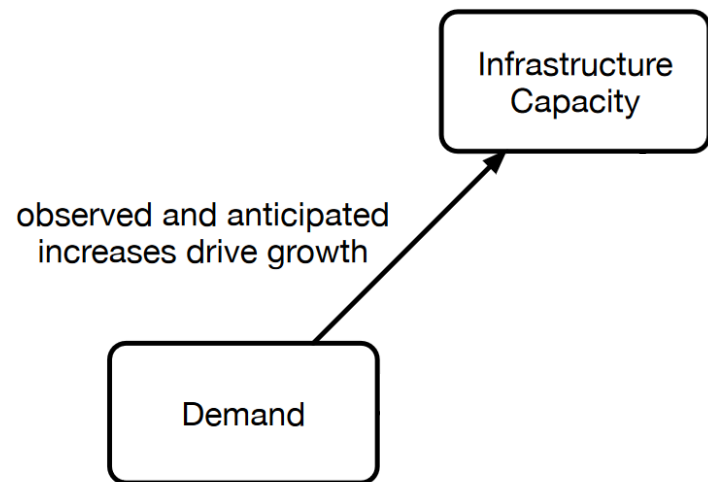

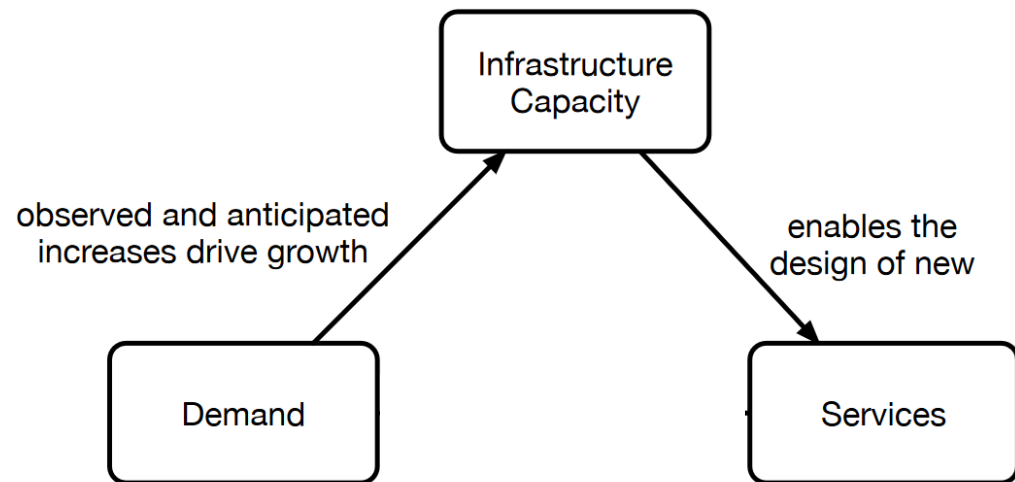

Do not forget

ISP overprovision networks to support

- Peak traffic
- Fault tolerance

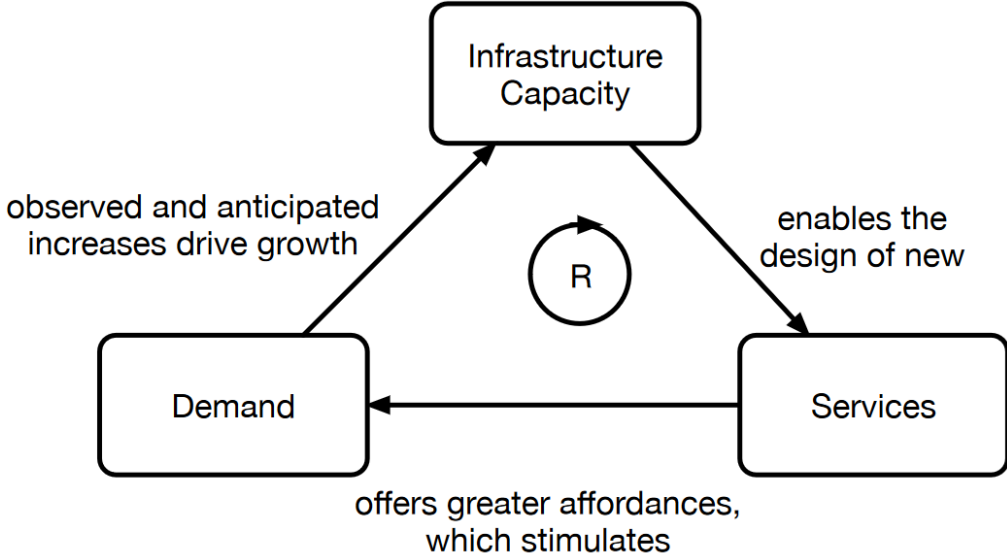

# There is a feedback loop that stimulates network capacity increase

There is a feedback loop that stimulates network capacity increase and energy usage.

# We must embrace some **digital sobriety**.

**Everything** has a **cost**.

- Every picture            we upload
- Every app                we download
- Every movie             we stream
- Every conversation    we archive

It is not to say we must not do it  
but

we must **be mindful** when doing it,  
and do it only when actually useful.

We must embrace some **digital sobriety**.

Everything has a cost.

- Every picture we upload
- Every app we download
- Every movie we stream
- Every conversation we archive

It is not to say we must not do it but we must **be mindful** when doing it, and do it only when actually useful.

That does **not** have to imply worse UX!

- Software bloat can be huge.
- Applications can be redesigned without assuming permanent high-speed connectivity.

That's where GreenIO folks come in!

... and what's  
with the Zoo?

The poster features the logos for Green IO Paris and apidays at the top. Below them, the event dates and location are listed: December 3rd, 4th and 5th, 2024, from 9:00 AM CET at CNIT Forest, La Défense. A portrait of Romain Jacob is on the left, and the text '3 questions to our speaker' is on the right, set against a background of a Parisian cityscape with the Eiffel Tower.

**Romain Jacob**

**3 questions to  
our speaker**

What is the most surprising word  
that you will use in your speech?

Zoo

# We have a data transparency problem for networking hardware.

- Vendors hardly provide any useful power info.
- Embedded power sensors are not trustworthy.
- There is no standard for power data reporting.

TL;DR

We need more power measurements and a systematic data collection.

# We created a public database for power data: Network Power Zoo

The database contains

- Datasheet information
- PSU readings
- External measurements
- Power models

Would you share  
your network's data?

We work on tools to make it easy 😊

Welcome to the
